WSTĘP

Zeszyt niniejszy obejmuje wyniki pomiarów i rejestracji niektórych elementów elektryczności atmosferycznej i dobowych obserwacji najważniejszych czynników meteorologicznych w Świdrze za 1960 rok. Dane za lata 1957-1959 opublikowane w Nr 16, 19, 20 Rocznika Obserwatorium Geofizycznego im. St. Kalinowskiego w Świdrze, tam też omówiono szczegółowo położenie stacji, sposób prowadzenia pomiarów, używaną aparaturę oraz sposób opracowania wyników. W niniejszym Roczniku podaje się krótko w celu przypomnienia tylko najważniejsze z tych informacji.

Świder ($\varphi = 52^{\circ}07'$, $\lambda = 21^{\circ}15'$, $h = 100$ m) leży około 25 km na południowy wschód od Warszawy i posiada parkowo-willowy charakter zagośpodařowanego. W jego okolicy brak jest większych zakładów przemysłowych. Obszar przyległy do Świdra charakteryzuje się dość dużą gęstością zaludnienia.

W 1960 roku wszystkie pomiary wykonywano tymi samymi przyrządami, co w roku poprzednim (1959). Anemograf f-my Fuess, który dotychczas był zainstalowany na wysokości 14 m nad powierzchnią gruntu został podwyższony (19 X 1960) do 17 m. O ile chodzi o inne przyrządy to pozostały one na dawnych miejscach.

Wartości natężenia pola elektrycznego zawarte w "Roczniku" stanowią przeliczenia wyników ciągłej rejestracji dwóch niezależnych układów złożonych z sond radioaktywnych podłączonych do elektrometrów Bendorca. Jeden z układów, czulszy, przeznaczony do notowania średnich wielkości natężenia pola elektrycznego, posiadał zakres wskazań od około -200 do +300 V/m, drugi układ, mniej czuły, przeznaczony do notowania większych wartości pola, obejmował zakres od około -700 do +900 V/m. W tablicach zestawiono średnie wartości godzinne (wg G.M.T.) i dobowe maksima, minima oraz amplitudy natężenia pola elektrycznego z poszczególnych miesięcy, uwzględniając współczynnik redukcyjny odnośnie powierzchni płaskiej. Do obliczeń wartości średnich dobowych, średnich miesięcznych dla poszczególnych godzin i średnich dla całego miesiąca użyto dane niepodkreślone i bez nawiasów półokrągłych. Wartości z okresów, kiedy wystąpił opad atmosferyczny, mgła, zamglenie i burza, podkreślono linią ciągłą, a dane niepewne umieszczone w nawiasach półokrągłych. Wartości pola elektrycznego poprzedzono znakiem $>$ lub $<$, gdy krzywa rejestracyjna dla danego przedziału godzinnego wyszła częściowo poza zakres w jednym lub drugim kierunku. W przypadku gdy w przedziale jednej godziny krzywa ta znalazła się częściowo poza zakresem w dodatnich wartościach a także dla tej samej godziny i w ujemnych wartościach, zaznaczono to znakiem \ddagger . Typ pogody każdej doby scharakteryzowano symbolami literowymi: b - niebo pogodne, o - niebo o zachmurzeniu umiarkowanym, c - niebo o zachmurzeniu dużym, r - deszcz, p - opad przelotny, s - opad śnieżny, d - mżawka, h - opad gradu, t - burza, l - błyskawica, f - mgła, m - mgiełka, n - zmętnienie pyłowe.

Dodatkowo wyjaśnia się, że na anormalnie niską wartość średniej miesięcznej natężenia pola elektrycznego w kwietniu wpłynęło głównie zmętnienie pyłowe atmosfery w dniach 7 i 8. To dość rzadko spotykane zjawisko powodowało utrzymywanie się bardzo niskich ujemnych wartości pola elektrycznego przez dłuższy okres doby w tych dwóch dniach. Wpływ zmętnienia 7 i 8 kwietnia uwidocznił się również i na wartościach przewodnictwa powietrza, a szołególnie w przewadze biegunkowej przewodnictwa ujemnego nad dodatnim (λ_+/λ_-).

Pomiary przewodnictwa powietrza wykonywano przyrządem Gerdiena, wyposażonym w jednonitkowy elektrometr Wulfa. Czas trwania pomiaru jednego biegunkowego znaku przewodnictwa wynosił 10 minut, zaś całkowitego przewodnictwa 20 minut. Tablice zawierają wartości przewodnictwa dodatniego (λ_+) i ujemnego (λ_-) z trzech terminów obserwacyjnych (I 5%).

- 6^h, II 11⁰⁰ - 14⁰⁰, III 19⁰⁰ - 19⁰⁰ G.M.T.), średnie dobowe obu znaków przewodnictwa (M dla λ_+ i M dla λ_-), średnie dobowe całkowitego przewodnictwa (M dla $\lambda_+ + \lambda_-$) i stosunek średniego dobowego przewodnictwa dodatniego do ujemnego (M dla λ_+/λ_-). Oprócz tego podano średnie miesięczne wartości przewodnictwa dla wszystkich wymienionych wyżej zestawień.

Ilość jader kondensacji w powietrzu mierzono małym licznikiem Scholza w tych samych terminach obserwacyjnych, jak pomiary przewodnictwa. Na podstawie wyników z trzech obserwacji w ciągu doby obliczono wartości średnich dobowych i średnich miesięcznych.

W zestawieniu miesięcznych tablic elementów meteorologicznych podano dla trzech terminów obserwacyjnych w ciągu doby (7^h, 13^h, 21^h wg czasu miejscowego) wartości ciśnienia atmosferycznego, temperatury powietrza, ciśnienia pary wodnej, wilgotności względnej powietrza, stopnia zachmurzenia i rodzaju chmur. Oprócz tego zestawiono dobową sumę opadu atmosferycznego, wysokość pokrywy śnieżnej i inne zjawiska meteorologiczne uwzględniając czas (miejscowy) ich wystąpienia oraz nasilenie (patrz "Uwagi"). Średnie dobowe wartości wszystkich elementów meteorologicznych obliczono z trzech pomiarów w ciągu doby a średnie miesięczne z wszystkich pomiarów terminowych.

Wyniki dotyczące stosunków termicznych gleby na głębokości 5, 10, 20, 50 cm i temperatury minimalnej powierzchni gleby zawarte są w oddzielnym tablicach miesięcznych. Podobnie jak i dla poprzednio wymienionych elementów meteorologicznych umieszczono odpowiednie wartości z godziny 7, 13, 21 (czasu miejscowego), średnie dobowe i średnie miesięczne. Ważne dla analizy procesów termicznych gleby będzie zwrócenie uwagi na fakt, że w Świdrze podłożem jest wybitnie piaszczyste, a powierzchnia wody gruntowej na terenie stacji występuje na głębokości około 5 m.

W 1960 roku pomiary elektryczności atmosferycznej i meteorologii prowadzili: S. Warzecha, Z. Haberk a, J. Kolačz, B. Ołdak i P. Łęgowski. W opracowaniu materiałów brały udział wszystkie wymienione wyżej osoby. Materiał do druku przygotował S. Warzecha. Koordynacją całości pracy zajmował się kierownik Obserwatorium Geofizycznego P A N w Świdrze Z. Kalinowska oraz S. Michnowski.

Świder, 24 października 1960 r.

Stanisław Warzecha

RÉSUMÉ

Le présent fascicule contient les résultats des mesures et de l'enregistrement de certains éléments choisis de l'électricité atmosphérique et ceux des observations diurnes (24 h.) des principaux facteurs météorologiques à Świder, pour l'année 1960. Les données pour les années 1957-1959 ont été publiées dans les Nr. 16, 19, 20 des Travaux de l'Observatoire Géophysique de St. Kalinowski à Świder; ces derniers contiennent également une description détaillée de la station, les procédés adoptés pour les mesures, l'équipement technique en usage et le mode d'élaboration des résultats obtenus. Le présent Annuaire ne fournit que les informations les plus importantes sur ces questions, rien que pour les rappeler au lecteur.

Świder ($\varphi = 52^{\circ}07'$, $\lambda = 21^{\circ}15'$, $h = 100$ m) est situé au Sud-Est de Varsovie, à une distance d'environ 25 km de cette ville. C'est une villégiature comprenant une espèce de parc naturel où des villas sont dispersées. Il n'y a aucun établissement industriel à proximité; cependant, la densité de la population des terrains avoisinants est assez élevée.

En 1960, toutes les mesures ont été effectuées avec les mêmes appareils que l'année précédente. L'anémographe Fuess qui, jusqu'ici, était installé à 14 m. au-dessus du sol, a été placé, le 19 X 1960, à une hauteur de 17 m. Les autres appareils et instruments sont restés à leur place.

Les valeurs de l'intensité du champ électrique figurant dans l'Annuaire ont été obtenues à partir des résultats de l'enregistrement continu du gradient du potentiel électrique au moyen de deux appareils indépendants, composés de sondes radioactives branchées sur des électro-

mètres Benndorf. L'un d'eux, d'une sensibilité plus grande est destiné à noter les valeurs moyennes de l'intensité du champ électrique (de -200 environ à +300 V/m), l'autre, d'une sensibilité moins grande, sert à noter les valeurs plus grandes de l'intensité de ce champ (de -700 environ à +900 V/m). Les tableaux contiennent les relevés des valeurs moyennes horaires (d'après G.M.T.) et les valeurs diurnes maxima et minima ainsi que les amplitudes de l'intensité du champ électrique pour les différents mois, compte tenu du coefficient de réduction par rapport à la surface plane. Les données se rapportent aux évaluations des moyennes diurnes, des moyennes mensuelles pour les différentes heures et des moyennes pour le mois entier figurent sur le tableau sans être soulignées d'une ligne continue et ne sont pas entre parenthèses.

Les valeurs obtenues en temps de précipitation atmosphérique, de brume, de brouillard et d'orage sont soulignées par une ligne continue; quant aux données incertaines, elles figurent entre parenthèses. Les valeurs du champ électrique sont précédées du signe > ou <, lorsque la courbe d'enregistrement dépasse partiellement le cercle dans la direction des valeurs positives ou négatives. Au cas, où la valeur du champ électrique pour le secteur horaire donné s'est trouvée partiellement dehors du cercle, dans la direction des valeurs positives et, pour la même heure, dans celle des valeurs négatives, on a utilisé le symbole \$. Le temps de chaque jour a été indiqué par les lettres suivantes: b - ciel serein, o - nébulosité modérée, c - nébulosité considérable, r - pluie, p - précipitation passagère (averse ou shover), s - neige, d - bruine, h - grêle, t - orage, l - éclair, f - brume, m - brouillard, z - nuage de poussière.

Nous expliquons, à titre supplémentaire, que la valeur anormalement basse de la moyenne mensuelle de l'intensité du champ électrique en avril a été due surtout à un nuage de poussière enregistré les 7 et 8 avril. Ce phénomène assez rare a contribué à réduire considérablement les valeurs négatives du champ électrique pendant ces deux jours, durant une grande partie de la journée (24 h.). L'influence de ce nuage de poussière s'est reflétée dans la valeur de la conductibilité de l'air et, tout particulièrement, elle s'est exprimée par la prépondérance de la conductibilité des pôles négative sur la conductibilité positive (λ_+/λ_-).

Les mesures de la conductibilité de l'air ont été effectuées avec l'appareil Gerdien, doté d'un électromètre Wulf à un fil. La durée de l'aspiration de l'air par le condensateur a été de 10 minutes pour chaque détermination de la conductibilité (positive ou négative), et 20 minutes pour la conductibilité totale. Les tableaux contiennent les valeurs de la conductibilité positive (λ_+) et négative (λ_-) pour 3 périodes d'observation comprenant les heures suivantes: I 5⁰⁰ - 6⁰⁰, II 11⁰⁰ - 14⁰⁰, III 19⁰⁰ - 19⁰⁰ G.M.T., les moyennes diurnes pour la conductibilité positive et négative (M pour λ_+ et M pour λ_-) et pour la conductibilité totale (M pour $\lambda_+ + \lambda_-$) et le rapport entre la conductibilité moyenne diurne positive et négative (M pour λ_+/λ_-). Outre cela, on a donné les valeurs moyennes mensuelles de la conductibilité pour tous les relevés susmentionnés.

Le degré de concentration des noyaux de condensation dans l'air a été mesuré à l'aide du petit compteur Scholz, les observations ayant été effectuées 3 fois en 24 h., comme pour les mesures de la conductibilité. C'est sur la base de ces observations qu'on a pu calculer les moyennes diurnes (24 h.) et mensuelles.

Le relevé des tableaux mensuels des éléments météorologiques fournit pour les trois périodes d'observation au cours de 24 h (7h, 13h, 21h, d'après le temps local) les valeurs de la pression atmosphérique, de la température de l'air, de la pression de la vapeur d'eau, de l'humidité relative de l'air, le degré de nébulosité et la mesure de la hauteur des précipitations atmosphériques diurnes (24h.), l'épaisseur de la couche de neige et la durée (suivant le temps local) des autres phénomènes météorologiques enregistrés ainsi que leur ampleur (voir "Mentions"). Les moyennes diurnes de tous les éléments météorologiques ont été calculées à partir des mesures prises trois fois par jour, et les moyennes mensuelles - sur la base de tous les mesures.

Pour ce qui est des conditions thermiques du sol, les résultats des mesures effectuées à une profondeur de 5, 10, 20 et 50 cm, ainsi que les mesures de la température minima à la surface du sol sont présentés dans des tableaux mensuels distincts. Comme pour les éléments météoro-

logiques sus-visés, sur ces tableaux figurent les résultats des mesures effectuées à 7, 13 et 21 h. G.M.T. ainsi que les moyennes diurnes et mensuelles. Pour l'analyse des processus thermiques du sol, il importe d'attirer l'attention sur le fait que le sol à Świder est essentiellement siliceux et que l'eau de fond apparaît à la station à une profondeur d'environ 5 m.

En 1960, les mesures de l'électricité atmosphérique et des éléments météorologiques ont été réalisées par: S. Warzecha, Z. H. aberk a, J. Kołacz, B. Olidak et P. Legowsk i. Toutes les personnes susmentionnées ont pris part à l'élaboration des matériaux. La fascicule a été préparés par S. Warzecha. Ce sont Z. Kalinowska, Chef de l'Observatoire Géophysique de l'Académie Polonaise des Sciences à Świder et S. Michnowski, qui ont assuré la coordination de l'ensemble des travaux.
